The Genetics Of Fleece Weight And Fibre Diameter: Between-flock variation

Produced for the CRC for Premium Quality Wool undergraduate program by;
Pat Taylor, NSW Agriculture.

Selecting Between Bloodlines

Bloodline CFW / FD Deviations 1984 - 1995 Wether Trial Analysis

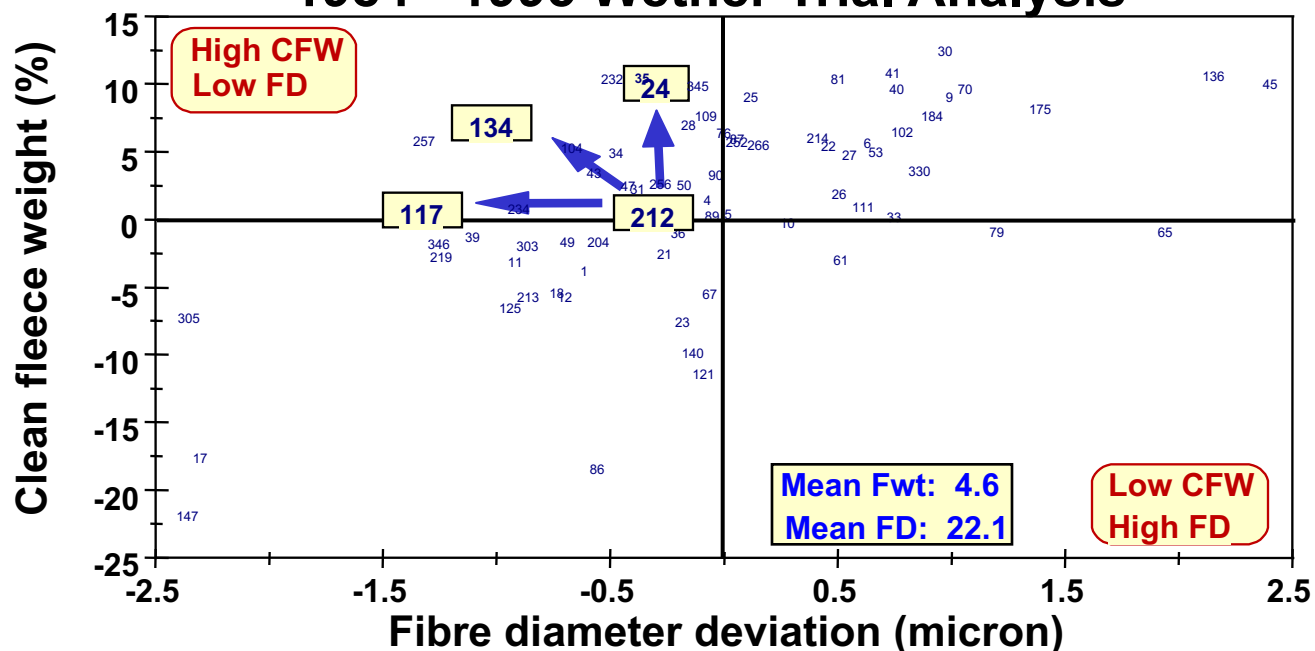

- 20% range in CFW among bloodlines of average diameter
- >3.0 μm range in MFD among bloodline of average fleece weight.
- Although bloodlines of higher CFW tend to have higher MFD there is excellent potential to simultaneously improve both.

1984 - 1995 Wether Trial Analysis

- Depending on the breeding objective a breeder may elect to improve CFW or MFD or both. For example:
- from 212 to 24 = +10% CFW
- from 212 to 117 = -1 μ m MFD
- from 212 to 134 = +7% CFW and -0.7 μ m

The relative profitability of different bloodlines is very dependent on micron premiums.

- Simultaneous improvement in CFW and MFD moderates the risk associated with setting breeding objectives based on uncertain future micron premiums.

Bloodline replacement

- **grading up to a new bloodline can be slow**
 - **for example, if a commercial breeder replaced all rams in year 1 and culled the original breeding ewes each year as young ewes enter the breeding flock, by year 10, ewes of breeding age will average about 80% of the new bloodline.**
- **ideally ewes from the new bloodline should be purchased as well**

Other considerations

- genetic progress in current bloodline
- genetic progress in new bloodline(s)
- over last 5 years and into the future
- depending on the cross, breeders should expect an extra 5% in CFW and 3% in body weight in the first cross due to heterosis
